

Example 2.1.

1. The set $\mathbb{Z} = \{\dots, -n, \dots, -1, 0, 1, \dots, n, \dots\}$ of integers is an abelian group under addition, with identity element 0. However, $\mathbb{Z}^* = \mathbb{Z} - \{0\}$ is not a group under multiplication.
2. The set \mathbb{Q} of rational numbers (fractions p/q with $p, q \in \mathbb{Z}$ and $q \neq 0$) is an abelian group under addition, with identity element 0. The set $\mathbb{Q}^* = \mathbb{Q} - \{0\}$ is also an abelian group under multiplication, with identity element 1.
3. Given any nonempty set S , the set of bijections $f: S \rightarrow S$, also called *permutations of S* , is a group under function composition (i.e., the multiplication of f and g is the composition $g \circ f$), with identity element the identity function id_S . This group is not abelian as soon as S has more than two elements. The permutation group of the set $S = \{1, \dots, n\}$ is often denoted \mathfrak{S}_n and called the *symmetric group on n elements*.
4. For any positive integer $p \in \mathbb{N}$, define a relation on \mathbb{Z} , denoted $m \equiv n \pmod{p}$, as follows:

$$m \equiv n \pmod{p} \quad \text{iff} \quad m - n = kp \quad \text{for some } k \in \mathbb{Z}.$$

The reader will easily check that this is an equivalence relation, and, moreover, it is compatible with respect to addition and multiplication, which means that if $m_1 \equiv n_1 \pmod{p}$ and $m_2 \equiv n_2 \pmod{p}$, then $m_1 + m_2 \equiv n_1 + n_2 \pmod{p}$ and $m_1 m_2 \equiv n_1 n_2 \pmod{p}$. Consequently, we can define an addition operation and a multiplication operation of the set of equivalence classes \pmod{p} :

$$[m] + [n] = [m + n]$$

and

$$[m] \cdot [n] = [mn].$$

The reader will easily check that addition of residue classes \pmod{p} induces an abelian group structure with $[0]$ as zero. This group is denoted $\mathbb{Z}/p\mathbb{Z}$.

5. The set of $n \times n$ invertible matrices with real (or complex) coefficients is a group under matrix multiplication, with identity element the identity matrix I_n . This group is called the *general linear group* and is usually denoted by $\mathbf{GL}(n, \mathbb{R})$ (or $\mathbf{GL}(n, \mathbb{C})$).
6. The set of $n \times n$ invertible matrices A with real (or complex) coefficients such that $\det(A) = 1$ is a group under matrix multiplication, with identity element the identity matrix I_n . This group is called the *special linear group* and is usually denoted by $\mathbf{SL}(n, \mathbb{R})$ (or $\mathbf{SL}(n, \mathbb{C})$).
7. The set of $n \times n$ matrices Q with real coefficients such that

$$QQ^\top = Q^\top Q = I_n$$
