

Definition 3.21. A linear map $f: E \rightarrow F$ is an *isomorphism* iff there is a linear map $g: F \rightarrow E$, such that

$$g \circ f = \text{id}_E \quad \text{and} \quad f \circ g = \text{id}_F. \quad (*)$$

The map g in Definition 3.21 is unique. This is because if g and h both satisfy $g \circ f = \text{id}_E$, $f \circ g = \text{id}_F$, $h \circ f = \text{id}_E$, and $f \circ h = \text{id}_F$, then

$$g = g \circ \text{id}_F = g \circ (f \circ h) = (g \circ f) \circ h = \text{id}_E \circ h = h.$$

The map g satisfying $(*)$ above is called the *inverse* of f and it is also denoted by f^{-1} .

Observe that Proposition 3.18 shows that if $F = \mathbb{R}^n$, then we get an isomorphism between any vector space E of dimension $|J| = n$ and \mathbb{R}^n . Proposition 3.18 also implies that if E and F are two vector spaces, $(u_i)_{i \in I}$ is a basis of E , and $f: E \rightarrow F$ is a linear map which is an isomorphism, then the family $(f(u_i))_{i \in I}$ is a basis of F .

One can verify that if $f: E \rightarrow F$ is a bijective linear map, then its inverse $f^{-1}: F \rightarrow E$, as a function, is also a linear map, and thus f is an isomorphism.

Another useful corollary of Proposition 3.18 is this:

Proposition 3.21. *Let E be a vector space of finite dimension $n \geq 1$ and let $f: E \rightarrow E$ be any linear map. The following properties hold:*

- (1) *If f has a left inverse g , that is, if g is a linear map such that $g \circ f = \text{id}$, then f is an isomorphism and $f^{-1} = g$.*
- (2) *If f has a right inverse h , that is, if h is a linear map such that $f \circ h = \text{id}$, then f is an isomorphism and $f^{-1} = h$.*

Proof. (1) The equation $g \circ f = \text{id}$ implies that f is injective; this is a standard result about functions (if $f(x) = f(y)$, then $g(f(x)) = g(f(y))$, which implies that $x = y$ since $g \circ f = \text{id}$). Let (u_1, \dots, u_n) be any basis of E . By Proposition 3.18, since f is injective, $(f(u_1), \dots, f(u_n))$ is linearly independent, and since E has dimension n , it is a basis of E (if $(f(u_1), \dots, f(u_n))$ doesn't span E , then it can be extended to a basis of dimension strictly greater than n , contradicting Theorem 3.11). Then f is bijective, and by a previous observation its inverse is a linear map. We also have

$$g = g \circ \text{id} = g \circ (f \circ f^{-1}) = (g \circ f) \circ f^{-1} = \text{id} \circ f^{-1} = f^{-1}.$$

(2) The equation $f \circ h = \text{id}$ implies that f is surjective; this is a standard result about functions (for any $y \in E$, we have $f(h(y)) = y$). Let (u_1, \dots, u_n) be any basis of E . By Proposition 3.18, since f is surjective, $(f(u_1), \dots, f(u_n))$ spans E , and since E has dimension n , it is a basis of E (if $(f(u_1), \dots, f(u_n))$ is not linearly independent, then because it spans E , it contains a basis of dimension strictly smaller than n , contradicting Theorem 3.11). Then f is bijective, and by a previous observation its inverse is a linear map. We also have

$$h = \text{id} \circ h = (f^{-1} \circ f) \circ h = f^{-1} \circ (f \circ h) = f^{-1} \circ \text{id} = f^{-1}.$$

This completes the proof. □
