in the least squares sense, subject to the conditions  $a_i^{\top} a_j = \delta_{ij}$ , for all i, j with  $1 \leq i, j \leq k$ , where the matrix of the system is a block diagonal matrix consisting of k diagonal blocks  $(X, \mathbf{1})$ , where  $\mathbf{1}$  denotes the column vector  $(1, \ldots, 1) \in \mathbb{R}^n$ .

Again it is easy to see that each hyperplane  $H_i$  must pass through the centroid  $\mu$  of  $X_1, \ldots, X_n$ , and by switching to the centered data  $X_i - \mu$  we get the system

$$\begin{pmatrix} X - \mu & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & X - \mu \end{pmatrix} \begin{pmatrix} a_1 \\ \vdots \\ a_k \end{pmatrix} = \begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix},$$

with  $a_i^{\top} a_j = \delta_{ij}$  for all i, j with  $1 \leq i, j \leq k$ .

If  $VDU^{\top} = X - \mu$  is an SVD decomposition, it is easy to see that a least squares solution of this system is given by the last k columns of U, assuming that the main diagonal of D consists of the singular values  $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_d$  of  $X - \mu$  arranged in descending order. But now the (d-k)-dimensional subspace  $U_{d-k}$  cut out by the hyperplanes defined by  $a_1, \ldots, a_k$  is simply the orthogonal complement of  $(a_1, \ldots, a_k)$ , which is the subspace spanned by the first d-k columns of U.

So the best (d-k)-dimensional affine subpsace  $A_k$  approximating  $X_1, \ldots, X_n$  in the least squares sense is

$$A_k = \mu + U_{d-k},$$

where  $U_{d-k}$  is the linear subspace spanned by the first d-k principal directions of  $X-\mu$ , that is, the first d-k columns of U. Consequently, we get the following interesting interpretation of PCA (actually, principal directions):

**Theorem 23.12.** Let X be an  $n \times d$  matrix of data points  $X_1, \ldots, X_n$ , and let  $\mu$  be the centroid of the  $X_i$ 's. If  $X - \mu = VDU^{\top}$  is an SVD decomposition of  $X - \mu$  and if the main diagonal of D consists of the singular values  $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_d$ , then a best (d - k)-dimensional affine approximation  $A_k$  of  $X_1, \ldots, X_n$  in the least squares sense is given by

$$A_k = \mu + U_{d-k},$$

where  $U_{d-k}$  is the linear subspace spanned by the first d-k columns of U, the first d-k principal directions of  $X - \mu$  ( $1 \le k \le d-1$ ).

**Example 23.11.** Going back to Example 23.10, a best 1-dimensional affine approximation  $A_1$  is the affine line passing through  $(\mu_1, \mu_2) = (1824.4, 5.6)$  of direction  $u_1 = (0.9995, 0.0325)$ .

**Example 23.12.** Suppose in the data set of Example 23.5 that we add the month of birth of every mathematician as a feature. We obtain the following data set.
